1 Introduction

1.1 References

(a) A sampling of vector bundle techniques, Lazarsfeld.

1.2 Divisors

Remark. Let X be a projective variety over $k = \bar{k}$.

A divisor is a formal sum,

$$D = \sum a_i D_i$$

for $a_i \in \mathbb{Z}$ and D_i is a codimension 1 subvariety. We also will allow $a_i \in \mathbb{Q}$ or \mathbb{R} .

Definition 1.2.1. $N^1(X)_{\mathbb{R}} = \{\mathbb{R}\text{-divisors}\}/\sim \text{where,}$

$$D_1 \sim D_2 \iff D_1 \cdot C = D_2 \cdot C$$

for all integral curves $C \subset X$.

Definition 1.2.2 (Ample). A Line bundle \mathcal{L} is *ample* if one of the following equivalent conditions hold,

- (a) $\mathcal{L}^{\otimes m}$ (for some $m \geq 0$) is very ample meaning \mathcal{L} defines an embedding $X \hookrightarrow \mathbb{P}^N$
- (b) for any coherent sheaf \mathscr{F} there exists $n(\mathscr{F})$ s.t. $m \geq n(\mathscr{F})$ implies $\mathscr{F} \otimes \mathcal{L}^{\otimes m}$ is globally generated
- (c) for any coherent sheaf \mathscr{F} there exists $n(\mathscr{F})$ s.t. $m \geq n(\mathscr{F})$ implies $H^i(X, \mathscr{F} \otimes \mathcal{L}^{\otimes m}) = 0$ for all i > 0
- (d) (over \mathbb{C}) positive in the sense of admiting a positive hermitian connection.

Theorem 1.2.3 (Nakai-Moishezon). On X a line bundle \mathcal{L} is ample if and only if

$$(\mathcal{L}^{\dim V} \cdot V) > 0$$

for all subvarieties $V \subset X$.

Definition 1.2.4. \mathcal{L} is nef (numerically effective) if,

$$(\mathcal{L} \cdot C) > 0$$

for all curves $C \subset X$.

Theorem 1.2.5 (Kleiman). If \mathcal{L} is net then for any subvariety $V \subset X$,

$$\mathcal{L}^{\dim V} \cdot V \ge 0$$

Remark. However, $\mathcal{L} \cdot C > 0$ does not imply that \mathcal{L} is ample meaning it does not imply that the intersection against all subvarities is positive.

Proposition 1.2.6. (a) non-negative linear combinations of nef divisors are nef.

- (b) if $f: X \to Y$ is proper and \mathcal{L} on Y is nef then $f^*\mathcal{L}$ is nef.
- (c) if $f: X \to Y$ is surjective and proper and $f^*\mathcal{L}$ is nef then \mathcal{L} is nef.

Corollary 1.2.7. (a) Let X be projective, D is a nef \mathbb{R} -divisor, and H is any ample \mathbb{R} -divisor. Then $D + \epsilon H$ is ample for all $\epsilon > 0$.

(b) fix \mathbb{R} -divisors D and H, if $(D + \epsilon H)$ is ample for all small $\epsilon > 0$ then D is nef.

Proof. For (2) we have,

$$D \cdot C = \lim_{\epsilon \to 0} (D + \epsilon H) \cdot C \ge 0$$

For (1) we need to show that,

$$(D + \epsilon H)^{\dim V} \cdot V > 0$$

for any subvariety $V \subset X$. Now,

$$(D + \epsilon H)^{\dim V} = [D^{\dim V} + \dots + (\epsilon H)^{\dim V}] \cdot V$$

Since D is nef, all the intersections are ≥ 0 and $\epsilon^{\dim V} H^{\dim V} \cdot V > 0$ because $\epsilon > 0$ and H is ample and thus we conclude.

Proposition 1.2.8. Let $f: X \to T$ be surjective, proper and \mathcal{L} is a line bundle on X. Suppose for some $t_0 \in T$, that L_{t_0} is nef on X_{t_0} . Then there exists a countable union of proper subvarities $B \subset T$ such that L_t is nef on X_t for all $t \notin B$.

Definition 1.2.9. The ample cone is,

$$Amp(X) = \{ D \in N^1(X)_{\mathbb{R}} \mid D \text{ is ample} \} \subset N^1(X)_{\mathbb{R}}$$

and the nef cone,

$$\operatorname{Nef}(X) = \{D \in N^1(X)_{\mathbb{R}} \mid D \text{ is nef}\} \subset N^1(X)_{\mathbb{R}}$$

The corollaries tell us that Amp(X) is an open convex cone and $\overline{Amp(X)} = Nef(X)$.

Example 1.2.10. $X = \mathbb{P}^1 \times \mathbb{P}^1$. Then $N^1(X)_{\mathbb{R}} = \mathbb{R} \langle F_1, F_2 \rangle$ with basis $F_i = [\pi_i^{-1}(\text{pt})]$. The F_i are both nef but $F_i^2 = 0$ so they are not ample. The ample cone is the first quadrant and the nef cone is the first quadrant plus the positive axes.

Example 1.2.11. Let E be an elliptic curve general in \mathcal{M}_1 . Let $X = E \times E$. Then,

$$N^1(X)_{\mathbb{R}} = \mathbb{R} \langle F_1, F_2, \Delta \rangle$$

Claim: any effective class on $X = E \times E$ is nef. Indeed this is because we can freely move classes by translation until they intersect properly.

Lemma 1.2.12. Let $X = E \times E$. A class $\alpha \in N^1(X)_{\mathbb{R}}$ is nef iff $\alpha^2 \geq 0$ and $\alpha \cdot h \geq 0$ for some ample h.

Proposition 1.2.13. Let X be a surface and D an integral divisor s.t. $D^2 > 0$ and $(D \cdot H) > 0$ for some ample H, then mD is effective for some m > 0.

Proof. Consider,

$$\chi(X, mD) = \frac{1}{2}(mD) \cdot (mD - K_X) + \chi(\mathcal{O}_X)$$

Now since $D^2 > 0$ we can make $\chi(X, mD) \to \infty$ as $m \to \infty$. Furthermore, $h^2(X, mD) = h^0(X, K_X - mD) = 0$ for large enough m if $D \cdot H > 0$. Otherwise, there would be an effective $D' \sim K_X - mD$ and then $D' \cdot H > 0$ since H is ample but $D' \cdot H = K_X \cdot H - mD \cdot H < 0$ for large enough m since $D \cdot H > 0$. Therefore, we must have $h^0(X, mD) \to \infty$ as $m \to \infty$.

Remark. This proves the previous lemma using that the nef cone is closed and that eny effective class is nef.

Remark. Back to the example, let $\alpha = xF_1 + yF_2 + z\Delta$ and $h = F_1 + F_2 + \Delta$. Applying the lemma gives the inequalities of the nef cone,

$$x + y + z \ge 0$$
 $xy + xz + yz \ge 0$

This is a round cone.

1.3 Schedule

- (a) Castelnuovo-Mumford regularity
- (b) Introduction to Brill-Noether Theory
- (c) Petri's condition and Brill-Noether Theory on K3 surfaces:

$$\mu_0: H^0(C,A) \otimes H^0(C,\omega_C \otimes A^{\vee}) \to H^0(C,\omega_C)$$

for a line bundle A and a curve C when is this injective?

- (d) Lazarsfeld-Mukai bundles on K3 surfaces.
- (e) Proof of the Brill-Noether-Petri.
- (f) $\dim = 2$ case of Fujita's conjecture.
- (g) Moduli of sheaves on K3s? Other topics?

2 Mumford-Castounovo Regularity

Theorem 2.0.1 (Serre Vanishing). Let $X \to \operatorname{Spec}(A)$ be proper and \mathcal{L} ample on X. Then for any $\mathscr{F} \in \mathfrak{Coh}(X)$ there is some $n(\mathscr{F})$ such that for all $n \geq n(\mathscr{F})$ and i > 0,

$$H^i(X, \mathscr{F} \otimes \mathcal{L}^{\otimes n}) = 0$$

Remark. Today we want to quantify how the minimal $n(\mathscr{F})$ grows.

Definition 2.0.2. Let $X = \mathbb{P}_k^n$. Let $\mathscr{F} \in \mathfrak{Coh}(X)$ and $m \in \mathbb{Z}$. Then \mathscr{F} is m-regular if,

$$H^{i}(X, \mathcal{F}(m-i)) = 0$$

for all i > 0. Then the regularity of \mathscr{F} is,

$$\operatorname{reg}(\mathscr{F}) = \inf\{m \in \mathbb{Z} \mid \mathscr{F} \text{ is } m\text{-regular}\}$$

Remark. If \mathscr{F} is supported on a finite set then $\operatorname{reg}(\mathscr{F}) = -\infty$. Otherwise $\operatorname{reg}\mathscr{F}$ is a finite number.

Example 2.0.3. Consider $X = \mathbb{P}^1 \times \mathbb{P}^1$ and $\mathcal{L} = \mathcal{O}_X(-1, -3)$. Then,

$$H^i(X,\mathcal{L}) = 0$$

for all i by Kunneth since $\mathcal{O}_{\mathbb{P}^1}(-1)$ has no cohomology. However,

$$\dim H^{i}(X, \mathcal{L}(1)) = \begin{cases} 0 & i \neq 1 \\ 1 & i = 1 \end{cases}$$

because,

$$H^1(X,\mathcal{L}(1)) \cong H^0(\mathbb{P}^1,\mathcal{O}_{\mathbb{P}^1}) \otimes H^1(\mathbb{P}^1,\mathcal{O}_{\mathbb{P}^1}(-2))$$

The cohomology can all vanish but can jump up after a *positive* twist. However, $reg(\mathcal{L}) = 3$ so after twisting three times the higher cohomology stays zero.

Example 2.0.4. $\mathscr{F} = \mathcal{O}_{\mathbb{P}^n}(a)$ is (-a)-regular. If $X \subset \mathbb{P}^n$ is a degree d-hypersurface then $\iota_*\mathcal{O}_X$ is (d-1)-regular.

Proposition 2.0.5. Let $\mathscr{F} \in \mathfrak{Coh}(X)$ be m-regular. Then for $k \geq 0$,

- (a) \mathscr{F} is (m+k)-regular
- (b) $\mathscr{F}(m+k)$ is generated by global sections
- (c) the natural map,

$$H^0(X, \mathscr{F}(m)) \otimes H^0(X, \mathcal{O}_X(k)) \twoheadrightarrow H^0(X, \mathscr{F}(m+k))$$

is surjective.

Proof. By flat base change, we can ssume that k is algebraically closed. Then we do induction on $n = \dim X$. For $\mathscr{F} \in \mathfrak{Coh}(X)$ the support Supp (\mathscr{F}) is a closed subscheme so it has finitely many components and hence there exists a hyperplane mising each generic point (using that k is infinite). Therefore, we get an exact sequence,

$$0 \longrightarrow \mathscr{F}(-1) \longrightarrow \mathscr{F} \longrightarrow \mathscr{G} \longrightarrow 0$$

with $\mathscr{G} = \iota_*(\mathscr{F}|_H)$ supported on $H \cong \mathbb{P}^{n-1}$. When n = 0 the statements are obvious. By the sequence, if \mathscr{F} is m-regular then \mathscr{G} is m-regular. By the induction hypothesis, \mathscr{G} is (m+k)-regular. Thus for i > 0 and $k \geq 0$ we have $H^i(X, \mathscr{G}(m+k-i)) = 0$ so if $H^i(X, \mathscr{F}(m+k-1-i)) = 0$ then $H^i(X, \mathscr{F}(m+k-i)) = 0$ so if \mathscr{F} is (m+(k-1))-reglar then \mathscr{F} is (m+k)-regular so by induction \mathscr{F} is (m+k)-regular for all $k \geq 0$ proving (a). Now, consider the diagram,

$$0 \longrightarrow H^{0}(\mathscr{F}(m+k-1)) \otimes \mathcal{O}_{X} \longrightarrow H^{0}(\mathscr{F}(m+k)) \otimes \mathcal{O}_{X} \longrightarrow H^{0}(\mathscr{G}(m+k)) \otimes \mathcal{O}_{X} \longrightarrow 0$$

$$\downarrow \qquad \qquad \downarrow \qquad \qquad \downarrow$$

$$0 \longrightarrow \mathscr{F}(m+k-1) \longrightarrow \mathscr{F}(m+k) \longrightarrow \mathscr{G}(m+k) \longrightarrow 0$$

Since \mathscr{F} is (m+k)-regular $H^1(X,\mathscr{F}(m+k-1))=0$ so the top sequence is short exact. By the induction hypothesis, for all $k\geq 0$ the map $H^0(\mathscr{G}(m+k))\otimes \mathcal{O}_X \twoheadrightarrow \mathscr{G}(m+k)$ is surjective (on H this is the induction hypothesis and outside H this hold because \mathscr{G} vanishes). By Serre, there is some $k\gg 0$ such that $\mathscr{F}(m+k)$ is globally generated and thus by downward induction we see that $\mathscr{F}(m+k)$ is globally generated for all $k\geq 0$ proving (b). Then consider the diagram,

$$H^{0}(X, \mathscr{F}(m)) \otimes H^{0}(X, \mathcal{O}_{X}(k-1)) \longrightarrow H^{0}(X, \mathscr{F}(m+k-1))$$

$$\downarrow \qquad \qquad \downarrow \qquad \qquad \downarrow$$

$$H^{0}(X, \mathscr{F}(m)) \otimes H^{0}(X, \mathcal{O}_{X}(k)) \longrightarrow H^{0}(X, \mathscr{F}(m+k))$$

$$\downarrow \qquad \qquad \downarrow \qquad \qquad \downarrow$$

$$H^{0}(\mathscr{G}(m)) \otimes H^{0}(H, \mathcal{O}_{H}(k)) \longrightarrow H^{0}(H, \mathscr{G}(m+k))$$

$$\downarrow \qquad \qquad \downarrow$$

$$0$$

By induction on n the bottom map is surjective. The bottom downward maps are surjective because \mathscr{F} and \mathscr{G} are m-regular so $H^1(X, \mathscr{F}(m-1)) = 0$ and likewise for \mathscr{G} . Now we use induction on k. The case k = 0 is clear so we can assume that the top map is surjective and thus the middle map is also surjective completing the induction step. Therefore,

$$H^0(X, \mathscr{F}(m)) \otimes H^0(X, \mathcal{O}_X(k)) \twoheadrightarrow H^0(X, \mathscr{F}(m+k))$$

is surjective proving (c).

Proposition 2.0.6. Given an exact sequence,

$$0 \longrightarrow \mathscr{F}_1 \longrightarrow \mathscr{F}_2 \longrightarrow \mathscr{F}_3 \longrightarrow 0$$

Then,

- (a) if \mathscr{F}_1 and \mathscr{F}_3 are m-regular then \mathscr{F}_2 is m-regular
- (b) if \mathscr{F}_1 is (m+1)-regular and \mathscr{F}_2 is m-regular then \mathscr{F}_3 is m-regular
- (c) if \mathscr{F}_2 is m-regular and \mathscr{F}_3 is (m-1)-regular then \mathscr{F}_1 is m-regular
- (d) $\operatorname{reg}(\mathscr{F}_1) \leq \max\{\operatorname{reg}(\mathscr{F}_2), \operatorname{reg}(\mathscr{F}_3) + 1\}$
- (e) $\operatorname{reg}(\mathscr{F}_2) < \max\{\operatorname{reg}(\mathscr{F}_1), \operatorname{reg}(\mathscr{F}_2)\}$
- (f) $\operatorname{reg}(\mathscr{F}_3) \le \max\{\operatorname{reg}(\mathscr{F}_1) 1, \operatorname{reg}(\mathscr{F}_2)\}\$

Proof. Consider the long exact sequence,

$$H^i(X, \mathscr{F}_1(m-i)) \longrightarrow H^i(X, \mathscr{F}_2(m-i)) \longrightarrow H^i(X, \mathscr{F}_3(m-i)) \longrightarrow H^{i+1}(X, \mathscr{F}_1(m-i))$$
DO THIS

Proposition 2.0.7. Consider a coherent resolution,

$$0 \longrightarrow \mathscr{F}_n \xrightarrow{\mathrm{d}_n} \mathscr{F}_{n-1} \xrightarrow{\mathrm{d}_{n-1}} \longrightarrow \cdots \longrightarrow \mathscr{F}_1 \xrightarrow{\mathrm{d}_1} \mathscr{F}_0 \xrightarrow{\mathrm{d}_0} \mathscr{F} \longrightarrow 0$$

with each \mathscr{F}_j is (m+j)-regular. Then \mathscr{F} is m-regular and $H^0(X,\mathscr{F}_0(m)) \twoheadrightarrow H^0(\mathscr{F}(m))$.

Proof. Given $H^i(X, \mathscr{F}_j(m+j-i)) = 0$ for all i > 0 and $j \ge 0$. We want to show that $H^i(X, \mathscr{F}(m-i)) = 0$. DO THIS

Proposition 2.0.8. A coherent sheaf $\mathscr{F} \in \mathfrak{Coh}(X)$ is m-regular iff there exists a resolution,

$$0 \longrightarrow \mathcal{O}_X(-m-(n+1))^{\oplus a_{n+1}} \longrightarrow \cdots \longrightarrow \mathcal{O}_X(-m-1)^{\oplus a_1} \longrightarrow \mathcal{O}_X(-m)^{\oplus a_0} \longrightarrow \mathscr{F} \longrightarrow 0$$

Proposition 2.0.9. Let $\mathscr{F} \in \mathfrak{Coh}(X)$ and \mathscr{E} a vector bundle. If \mathscr{F} is m-regular and \mathscr{E} is ℓ -regular then $\mathscr{F} \otimes \mathscr{E}$ is $(m + \ell)$ -regular.

Proof. We apply the resultion property to \mathscr{F} and then applying $-\otimes \mathcal{E}$ gives a resultion of $\mathscr{F} \otimes \mathcal{E}$ since \mathcal{E} is flat. Then we apply the previous proposition.

Corollary 2.0.10. If \mathcal{E} is a an *m*-regular vector bundle then,

- (a) $\mathcal{E}^{\otimes r}$
- (b) $\bigwedge^r \mathcal{E}$
- (c) $S^r \mathcal{E}$ (for characteristic zero).

all are (rm)-regular.

Proof. Regularity of $\mathcal{E}^{\otimes r}$ is immediate. Then consider the exact sequence,

$$0 \longrightarrow I \longrightarrow \mathcal{E}^{\otimes r} \longrightarrow \bigwedge^r \mathcal{E} \longrightarrow 0$$

which has a section (CHECK)

Definition 2.0.11. Let X be a projective variety and \mathcal{L} a globally generated line bundle. Then \mathscr{F} is m-regular with respect to \mathcal{L} if,

$$H^i(X, \mathscr{F} \otimes \mathcal{L}^{\otimes (m-i)}) = 0$$

for all i > 0.

Proposition 2.0.12 (Green's Theorem). Let $W \subset H^0(X, \mathcal{O}_X(d))$ be a codimension n basepoint-free linear system. Then for $k \geq c$,

$$\zeta_k: W \otimes H^0(X, \mathcal{O}_X(k)) \twoheadrightarrow H^0(X, \mathcal{O}_X(d+k))$$

is surjective.

Proof. Consider $W \otimes \mathcal{O}_X$ then there is a map,

$$W \otimes \mathcal{O}_X \twoheadrightarrow \mathcal{O}_X(d)$$

which is surjective as a map of sheaves since W is base-point free. Let \mathcal{M}_W be its kernel. Then surjectivity is equivalent to $H^1(X, \mathcal{M}_W(k)) = 0$. Similarly, define,

$$0 \longrightarrow \mathcal{M}_d \longrightarrow H^0(X, \mathcal{O}_X(d)) \otimes \mathcal{O}_X \longrightarrow \mathcal{O}_X(d) \longrightarrow 0$$

Wind that \mathcal{M}_d is 1-regular and $\bigwedge^k \mathcal{M}_d$ is k-regular. Since codim (W) = c we have,

$$0 \longrightarrow \mathcal{M}_W \longrightarrow \mathcal{M}_d \longrightarrow \mathcal{O}_X^{\otimes c} \longrightarrow 0$$

Using the Egan-Northcott complex we have \mathcal{M}_W is (c+1)-regular. If $k \geq c$ then \mathcal{M}_W is (k+1)-regular and thus,

$$H^1(X, \mathcal{M}_W(k)) = H^1(X, \mathcal{M}_W(k+1-1)) = 0$$

Conjecture 2.0.13 (Fujita). Let X be a smooth projective variety $\dim X = n$. Let D be an ample divisor. Then,

- (a) $k \ge n + 1$ implies that $K_X + kD$ is basepoint free
- (b) $k \ge n + 2$ implies that $K_X + kD$ is very ample.

Remark. This is true for curves, surfaces, and projective spaces.

Remark. h^0 can be hard to compute but χ is easier. If $H^i = 0$ for i > 0 then $\chi = h^0$.

Example 2.0.14. Let $X \subset \mathbb{P}^r$. What is the dimension of quadtric supersurfaces containing X. Consider $h^0(\mathscr{I}_X(2))$. We have,

$$0 \longrightarrow \mathscr{I}_X(2) \longrightarrow \mathscr{O}_{\mathbb{P}^r}(2) \longrightarrow \mathscr{O}_X(2) \longrightarrow 0$$

Therefore, we need vanishing $H^1(\mathscr{I}_X(2)) = 0$ to compute $h^0(\mathscr{I}_X(2))$.

Example 2.0.15. Let $\ell \subset \mathbb{P}^3$ be a line. What is the dimension of degree d surfaces containing ℓ . Since ℓ is a complete intersection $\ell = H_1 \cap H_2$ for two hyperplanes. We have a Kozul resolution,

$$0 \longrightarrow \mathcal{O}(-2) \longrightarrow \mathcal{O}(-1) \oplus \mathcal{O}(-1) \longrightarrow \mathcal{O} \longrightarrow 0$$

By the previous result, $H^0(\mathcal{O}) \to H^0(\mathcal{O}_\ell)$ is surjective and thus $H^1(\mathscr{I}_\ell(d)) = 0$. Alternatively, the resultion gives that \mathscr{I}_ℓ is 0-regular.

Example 2.0.16. Noether-Lefschetz: Pic $(S_d) = \mathbb{Z}$ for very general hypersurface $S_d \subset \mathbb{P}^3$ of degree d. However, if $S_d \supset \ell$ then it is not very general.

Example 2.0.17. Let $H_1, \ldots, H_e \subset \mathbb{P}$ be hypersurfaces with deg $H_i = d_i$ and a complete intersection,

$$X = H_1 \cap \cdots \cap H_e$$

Then,

$$reg(\mathscr{I}_X) = d_1 + \dots + d_e - e + 1$$

3 Andres: Moduli of Vector Bundles on Curves

Let C be a curve a smooth projective curve over k. Vector bundles on C vary in continuous families.

Example 3.0.1. If C is an elliptic curve then there is a bijection between,

$$C(k) \xrightarrow{\sim} \{\text{rank 1 vector bundles of degree 1}\}$$

via the map,

$$p \mapsto \mathcal{O}_C(p) \cong \mathscr{I}_p^{\vee}$$

Let $\Sigma_{n,d}$ be the set of all vector bundle s on C of fixed rank n and degree d. Assume that (n,d) = 1. We want that $\Sigma_{n,d}$ is the k-points of some projective variety.

Let T be a variety or a scheme, we can consider a vector bundle \mathcal{E} on $T \times C$ this gives a map $T(k) \to \Sigma_{n,d}$ via $t \mapsto \mathcal{E}_{C_t} \in \Sigma_{n,d}$. Therefore, we use this as the functor of points of the desired variety.

Consider the finest topology on $\Sigma_{n,d}$ such that for all T and all \mathcal{E} on $C \times T$ the induced map $T(k) \to \Sigma_{n,d}$ is continuous.

4 Brill-Noether Theory

Let C be a smooth projective curve of genus g. Then we want to consider the space of line bundles \mathcal{L} on C with $V \subset H^0(C, \mathcal{L})$ of dimension r+1 giving a map $C \dashrightarrow \mathbb{P}^r$ of degree d. We get a moduli space $G^r_d(C)$. We ask the following questions:

- (a) when is $G_d^r(C)$ nonempty
- (b) what is the dimension of $G_d^r(C)$
- (c) how many components does $G_d^r(C)$ have and are they equidimensional?

Definition 4.0.1. The Brill-Noether number,

$$\rho = g - (r+1)(g-d+r)$$

is the "expected dimension" of $G_d^r(C)$ for a general curve C.

Definition 4.0.2. There is a universal fibration $\mathscr{G}_d^r \to \mathcal{M}_g$ of the Brill-Noether moduli spaces.

Theorem 4.0.3 (Brill-Noether). There is an open locus of \mathcal{M}_g such that if,

- (a) $\rho < 0$ then $\mathcal{G}_d^r|_U$ is empty
- (b) $\rho \geq 0$ then $\mathscr{G}_d^r|_U$ has constant fiber dimension ρ and is smooth
- (c) $\rho > 0$ then \mathscr{G}_d^r has connected fibers (over all of \mathcal{M}_g).

Remark. If $\rho \geq 0$ then $G_d^r(C)$ is nonempty for all C but need not be smooth or of the correct dimension.

Example 4.0.4. Hyperelliptic curves have nontrivial \mathfrak{g}_2^1 but

$$\rho = g - 2(g - 1) = 2 - g$$

is negative for large g .

Definition 4.0.5. Consider the space

$$W_d^r(C) = \{ \mathcal{L} \mid \mathcal{L} \text{ line bundle wth } \deg \mathcal{L} = d \text{ and } \dim H^0(C, \mathcal{L}) \geq r + 1 \}$$

Then clearly there is a map $\beta: G_d^r(C) \to W_d^r(C)$.

4.1 Definition of Moduli Spaces

Definition 4.1.1. Let F_1, F_2 be free modules of finite rank over R and consider,

$$F_1 \xrightarrow{\varphi} F_2 \longrightarrow M \longrightarrow 0$$

Then the a^{th} fitting ideal $\operatorname{Fitt}_a(M)$ is the ideal generated by the $(\operatorname{rk} F_2 - a) \times (\operatorname{rk} F_{@} - a)$ minors of the matrix representing φ . This is independent of the presentation.

Definition 4.1.2. Using the universal line bundle \mathcal{L} on $C \times \operatorname{Pic}_C^d$ we define,

$$W_d^r(C) = \text{Fitt}_{q-d+r-1}(R^1 \nu_* \mathcal{L})$$

where $\nu: C \times \operatorname{Pic}_C^d \to \operatorname{Pic}_C^d$.

Remark. Notice that $R^1\nu_*\mathcal{L}$ has fibers $H^1(C,L)$ over the point [L] for L of degree d. Choose high enough degree divisor Γ on C we get,

$$0 \longrightarrow L \longrightarrow L(\Gamma) \longrightarrow L(\Gamma)/L \longrightarrow 0$$

Then the long exact sequence gives,

$$0 \, \longrightarrow \, H^0(C,L) \, \longrightarrow \, H^0(C,L(\Gamma)) \, \stackrel{\gamma}{\longrightarrow} \, H^0(C,L(\Gamma)/L) \, \longrightarrow \, H^1(C,L) \, \longrightarrow \, 0$$

Then by Riemann-Roch $h^0(C, L(\Gamma)) = d - g + 1 + m$ and $h^0(C, L(\Gamma)/L) = m$ where deg $\Gamma = m$. Then we have,

$$|W^r_d(C)| = \{L \in \operatorname{Pic}^d \mid \operatorname{rank} \gamma \leq m - (g - d + r - 1) - 1 = m - g + d - r\}$$

which is exactly the conditions of the fitting ideal.

Remark. Naive dimension count for $W_d^r(C)$ is,

$$\dim \mathrm{Pic}_C^d - \#\{\mathrm{minors}\} = g - (m - (m - g + d - r))(d - g + 1 + m - (m - g + d - r)) = g - (r + 1)(g - d + r) = \rho$$

4.2 Petri's Condition

Let C be a smooth projective curve. We say that C satisfies (P) if for all $\mathcal{L} \in \text{Pic}(C)$,

$$\mu_{\mathcal{L}}: H^0(C, \mathcal{L}) \otimes H^0(C, \omega_C \otimes \mathcal{L}^{\otimes -1}) \to H^0(C, \omega_C)$$

is injective.

Theorem 4.2.1 (Gieseker). Petri's condition holds for a general C.

Corollary 4.2.2. (a) If $\rho < 0$, for a general C, then G_d^r and W_d^r are empty

- (b) if $\rho \geq 0$, for a general C, then G_d^r is smooth of diemension ρ and W_d^r is smooth away from W_d^{r+1} and has dimension ρ
- (c) if $\rho \geq 1$, for a general C, then G_d^r and W_d^r are irreducible.

Proof. Consider infinitessimal deformation theory, given $(L,V) \in G_d^r(\mathbb{C})$ we consider,

$$T_{(L,V)}G_d^r = \{(L',V') \mid L' \text{ extending } L \text{ and } V' \subset H^0(L') \text{ free restricting to } V\}$$

The tangent space fits into a sequence,

$$0 \longrightarrow T_{(L,V)}\beta^{-1}(L) \to T_{(L,V)}G_d^r \stackrel{\beta}{\longrightarrow} T_L \operatorname{Pic}^d$$

and recall that $T_L \operatorname{Pic}^d \xrightarrow{\sim} H^1(C, \mathcal{O}_C)$.

When does $\phi \in T_L \operatorname{Pic}^d$ lie in the image of $T\beta$? We can represent ϕ by a Cech 1-cocycle $\phi_{\alpha\beta} \in \mathcal{O}_C(U_{\alpha\beta})$. For a given $[L] \in H^1(C, \mathcal{O}_C^{\times})$ represented by a cocycle $\{g_{\alpha\beta}\}$ then we can represent the lift with a given class by the cocycle $\{g'_{\alpha\beta} = g_{\alpha\beta}(1 + \epsilon \phi_{\alpha\beta})\}$. There needs to exist an extension (L, s) to (L', s') for $s \in W \subset H^0(L)$. For s' to be an extension of s we should have,

$$s'_{\alpha} = s_{\alpha} + \epsilon t_{\alpha}$$

for $t_{\alpha} \in \mathcal{O}_{\mathcal{C}}(U_{\alpha})$ and we want $s'_{\beta} = g'_{\alpha\beta}s'_{\alpha}$. This gives,

$$-\phi_{\alpha\beta}s_{\alpha} = t_{\alpha} - g_{\beta\alpha}t_{\beta}$$

Therefore we require that $-\phi \cdot s$ is zero in $H^1(L)$.

Thus $\phi \in \operatorname{im} T\beta$ is zero precisely when $\phi \cdot W \subset H^1(L)$ is zero. Therefore,

$$\operatorname{im} T\beta = \{ \phi \in H^1(\mathcal{O}_C) \mid \phi \cdot W = 0 \} = \{ \phi \in H^1(\mathcal{O}_C) \mid \forall s : \langle \phi W, s \rangle = 0 \}$$
$$= \{ \phi \in H^1(\mathcal{O}_C) \mid \forall s : \langle \phi, W \cdot s \rangle = 0 \}$$
$$= \{ \phi \in H^1(\mathcal{O}_C) \mid \langle \phi, t \rangle = 0 \}$$

over all $t \in \operatorname{im}(H^0(L) \otimes H^0(\omega_C \otimes L^{-1}) \to H^0(\omega_C))$. Therefore,

$$\dim T_{(L,W)}G_d^r = \dim \operatorname{im} T\beta + (r+1)(h^0(L) - (r+1))$$

using that $\beta^{-1}(L)$ is a Grasmannian and thus,

$$T_{(L,V)}\beta^{-1}(L) = \operatorname{Hom}\left(W, H^0(L)/W\right)$$

Therefore,

$$\dim T_{(L,W)}G_d^r = g - \dim \operatorname{im} \mu_L + (r+1)(h^0(L) - (r+1))$$

$$= g - ((r+1)h^0(\omega_C \otimes L^{-1}) - \ker \mu_L) + (r+1)(h^0(L) - (r+1))$$

$$= g + (r+1)(h^0(L) - h^0(\omega_C \otimes L^{-1}) - (r+1)) + \ker \mu_L$$

$$= g + (r+1)(g - g - r) + \ker \mu_L$$

$$= \rho + \ker \mu_L$$

Therefore, G_d^r has tangent space of the expected imension iff μ_L is injective. We already know dim $G_d^r \ge \rho$ from the naive dimension count. Then G_d^r is smooth at (L, W) of dimension ρ iff $\mu_L|_W$ is injective.

Then $\beta: G_d^r \to W_d^r$ is an siomrophism away from W_d^{r+1} and $W_d^r \setminus W_d^{r+1}$ is dense in W_d^r . Furthermore, μ_L is injective implies that W_d^r is smooth of dim $= \rho$ away from W_d^{r+1} .

4.3 Riemann-Roch in Geometric Terms

Let D be an effective divisor. Then,

$$r(D) = h^0(D) - 1$$

is the number of independent relations between the canonical image $\phi(D)$ meaning under the canonical embedding $\phi: C \to \mathbb{P}^{g-1}$.

Example 4.3.1. If C is hyperelliptic and D is degree d effective divisor with r(D) = r. Then,

$$D \sim r\mathfrak{g}_2^1 + p_1 + \dots + p_{d-2r}$$

Example 4.3.2. If g = 4 and d = 3 and r = 1 then $\rho = 0$. If C is hyperelliptic then,

$$D = \mathfrak{g}_2^1 + p$$

and therefore $W_3^1 \cong C$ is 1-dimensional. If C is not hyperelliptic then under the canonical embedding $C \hookrightarrow \mathbb{P}^3$ we have $C = Q \cap S$ for a quadric Q and a cubic S surface. Then if D is degree 3 and r(D) = 1 then $\phi(D)$ should be colinear and hence the line is on Q. Therefore, W_3^1 is the set of linear equivalence classes of rullings on Q so $\#W_3^1 = 1$ if Q is a cone and $\#W_3^1 = 2$ if Q is smooth.

5 Oct 11. Brill Noether Theory on K3 Surfaces, Lazarsfeld-Mukai bundles

Definition 5.0.1. X/\mathbb{C} is a K3-surface if it is a smooth, projective variety of dim X=2 such that $K_X=\Omega^2_{X/K}\cong\mathcal{O}_X$ and $H^1(X,\mathcal{O}_X)=0$.

Example 5.0.2. Let $X \subset \mathbb{P}^3$ be a smooth quartic then $\omega_X = \omega_{\mathbb{P}^3} \otimes \mathcal{O}_X(4) \cong \mathcal{O}_X$.

Lemma 5.0.3. Let X be a K3 surface then $\chi(X, \mathcal{O}_X) = 2$.

Proof.
$$\chi = h^0 - h^1 + h^2 = 2h^0 = 2$$
.

Proposition 5.0.4. Let $C \subset X$ be a smooth irreducible curve of genus ≥ 1 then |C| has no base points and defines a morphism $\phi: X \to \mathbb{P}^g$ such that $\phi|_C: X \to \mathbb{P}^{g-1}$ is the canonical one.

Proof. The sequence,

$$0 \longrightarrow \mathcal{O}_X \longrightarrow \mathcal{O}_X(C) \longrightarrow \mathcal{O}_C(C) \longrightarrow 0$$

and use that $H^1(X, \mathcal{O}_X) = 0$ and thus,

$$H^0(X, \mathcal{O}_X(C)) \twoheadrightarrow H^0(C, \mathcal{O}_C(C)) = H^0(C, \omega_C)$$

Lemma 5.0.5. Let $C \subset X$ be a smooth irreducible curve with $g \geq 1$ and $\mathcal{L} = \mathcal{O}_X(C)$. Then $c_1(\mathcal{L})^2 = 2g - 2$ and $h^0(X, \mathcal{L}) = g + 1$. Also, if $\ell \geq 1$ then $h^0(X, \mathcal{L}^{\ell}) = (\ell^2/2)c_1(\mathcal{L})^2 + 2 = (g-1)\ell^2 + 2$.

Proof. Riemann-Roch gives,

$$2g - 2 = C \cdot (C + K_X) = \mathcal{L}^2$$

Then Riemann-Roch for surfaces gives,

$$\chi(X, \mathcal{L}) = \frac{1}{2}c_1(\mathcal{L})^2 + 2 = g + 1$$

also $h^2(X, \mathcal{L}) = h^0(X, \mathcal{L}^{\vee}) = 0$. Therefore,

$$h^0(X,\mathcal{L}) \ge q+1$$

Furthermore, $h^1(X, \mathcal{L}) = 0$ by Kodaira vanishing or something else.

Theorem 5.0.6. Let $C \subset X$ be a smooth irreducible curve of genus $g \geq 2$. Suppose every divisor in |C| is reduced and irreducible then,

- (a) for all $\mathcal{L} \in \text{Pic}(C)$ the number $\rho(\mathcal{L}) = g(C) h^0(\mathcal{L})h^1(\mathcal{L}) \geq 0$
- (b) Petri's condition holds for a general member $C' \in |C|$.

Remark. The assumption on the linear series is essential. For a counterexample, let |C| = |nD| with $D \subset X$ a curve of genus $g \geq 2$ and $n \geq 2$. Let $\mathcal{L} = \mathcal{O}_X(D)|_D$. Claim that $\rho(\mathcal{L}) < 0$. Consider the exact sequence,

$$0 \longrightarrow \mathcal{O}_X(D-C) \longrightarrow \mathcal{O}_X(D) \longrightarrow \mathcal{O}_C(D) \longrightarrow 0$$

5.1 Lazarsfeld-Mukai Bundle

From now on, X is a K3 surface and $C \subset X$ is a smooth irreducible curve. Recall that $V_d^r(C) \subset \operatorname{Pic}^d(C)$ is the open subset of $W_d^r(C)$ consisting of line bundles \mathcal{L} such that,

- (a) $h^0(\mathcal{L}) = r + 1$ and $\deg \mathcal{L} = d$
- (b) \mathcal{L} and $\omega_C \otimes \mathcal{L}^{\vee}$ are globally generated.

Definition 5.1.1. Fix $\mathcal{L} \in V_d^r(C)$. Let $\iota : C \hookrightarrow X$ be the inclusion. For each pair (C, \mathcal{L}) define, $\mathscr{F}_{C,\mathcal{L}}$ as the kernel of,

$$\operatorname{ev}: H^0(\mathcal{L}) \otimes_{\mathbb{C}} \mathcal{O}_X \twoheadrightarrow \iota_* \mathcal{L}$$

Lemma 5.1.2. Let \mathcal{E} be a vector bundle on X with a surjection $\varphi : \mathcal{E}|_{C} \twoheadrightarrow \mathcal{L}$. Then consider the exact sequence,

$$0 \longrightarrow \mathscr{F} \longrightarrow \mathcal{E} \longrightarrow \iota_* \mathcal{L} \longrightarrow 0$$

Then \mathscr{F} is locally free.

Proof. Work locally, assume $\mathcal{L} = \mathcal{O}_X$. Then there is a locally free resolution,

$$0 \longrightarrow \mathcal{O}_X(-C) \longrightarrow \mathcal{O}_X \longrightarrow \mathcal{O}_C \longrightarrow 0$$

Therefore the homological dimension of \mathcal{L} is ≤ 1 and therefore the homological dimension of \mathscr{F} is 0 and thus \mathscr{F} is locally free.

Corollary 5.1.3. The Lazarsfeld-Mukai bundle $\mathscr{F}_{C,\mathcal{L}}$ is a vector bundle.

Proof. Consider the sequence,

$$0 \longrightarrow \mathscr{F} \longrightarrow H^0(\mathcal{L}) \otimes_{\mathbb{C}} \mathcal{O}_X \longrightarrow \iota_* \mathcal{L} \longrightarrow 0$$

and apply the previous lemma.

Lemma 5.1.4. Let $\mathscr{F} = \mathscr{F}_{C,\mathcal{L}}$. Then,

- (a) \mathscr{F}^{\vee} is globally generated
- (b) $c_1(\mathscr{F}) = -[C]$ and $c_2(\mathscr{F}) = \deg \mathscr{F} = d$

(c)
$$H^0(\mathscr{F}) = H^2(\mathscr{F}^{\vee}) = 0$$
 and $H^1(\mathscr{F}) = H^2(\mathscr{F}^{\vee}) = 0$ and,

$$h^0(\mathscr{F}^\vee) = h^0(\mathcal{L}) + h^1(\mathcal{L})$$

Proof. Consider the sequence,

$$0 \longrightarrow H^0(\mathcal{L})^{\vee} \otimes \mathcal{O}_X \longrightarrow \mathscr{F}^{\vee} \longrightarrow \iota_*(\omega_C \otimes \mathcal{L}^{\vee}) \longrightarrow 0$$

By assumption the third term is globally generated and $H^0(\mathscr{F}^{\vee}) \twoheadrightarrow H^0(\mathfrak{m}_C \otimes \mathcal{L}^{\vee})$ because $H^1(X, \mathcal{O}_X) = 0$. Therefore, \mathscr{F}^{\vee} is globally generated.

In general we have a formula,

$$c_1(\iota_*\mathcal{L}) = [C] \quad c_2(\iota_*\mathcal{L}) = [C]^2 - \iota_*c_1(\mathcal{L}) = [C]^2 - (\deg \mathcal{L})[pt]$$

Then from the exact sequence,

$$0 \longrightarrow \mathscr{F} \longrightarrow H^0(\mathcal{L}) \otimes \mathcal{O}_X \longrightarrow \iota_* \mathcal{L} \longrightarrow 0$$

We get that,

$$c_1(\mathscr{F}) = -c_1(\mathcal{L}) = -[C] \quad c_2(\mathscr{F}) = -c_1(\iota_*\mathcal{L})c_1(\mathscr{F}) - c_2(\iota_*\mathcal{L}) = [C]^2 - [C]^2 + (\deg \mathcal{L})[pt] = (\deg \mathcal{L})[pt]$$

Lemma 5.1.5. Let $\mathscr{F} = \mathscr{F}_{C,\mathcal{L}}$ then,

$$\chi(\mathscr{F}\otimes\mathscr{F}^{\vee})=8-\Delta(\mathscr{F})=8+C^2-4\deg\mathcal{L}$$

6 Oct 18

6.1 Proof of (a)

Theorem 6.1.1 (Main). Let $C \subset X$ be a smooth irreducible curve of genus $g \geq 2$ on the K3 surface X. Assume that every divisor in the linear series |C| is reduced and irreducible. Then,

- (a) for each $\mathcal{L} \in \text{Pic}(C)$ we have $\rho(\mathcal{L}) \geq 0$
- (b) Petri's condition holds for a general element $C' \in |C|$.

Lemma 6.1.2. Let $\mathcal{L} \in \operatorname{Pic}(C)$ for a smooth proper curve C with $\deg \mathcal{L} \in (0, 2g - 2)$. There is a line bundle $\mathcal{L} = \mathcal{L}'(D)$ such that \mathcal{L}' and $\omega_C \otimes \mathcal{L}'^{\vee}$ are globally generated and $\rho(\mathcal{L}') \leq \rho(\mathcal{L})$.

Proof. Let D_1 be the divisor of base points of \mathcal{L} . Then $\mathcal{L}(-D_1)$ is globally generated because $|\mathcal{L}| = |\mathcal{L}(-D_1)| + D_1$. Let D_2 be the divisor of basepoints of $K_C - c_1(\mathcal{L}) + D_1$. Then $K_C - c_1(\mathcal{L}) + D_1 - D_2$ is base-point free. I claim that $\mathcal{L}(D_2 - D_1)$ is also globally generated. If $\mathcal{L}(D_2 - D_1 - P)$ does not drop dimension then by Riemann Roch $K_C - c_1(\mathcal{L}) + D_1 + P - D_2$ must increase dimension

Proof of (a). Suppose that $\rho(\mathcal{L}) < 0$ (REPLACE WITH BPF)

Let $\mathcal{E} = \mathscr{F}_{C,\mathcal{L}}^{\vee}$ which is a vector bundle since $\mathcal{L} \in V_d^r(C)$. We showed that,

$$2h^0(X, \mathscr{F} \otimes \mathscr{F}^{\vee}) > \chi(\mathscr{F}, \mathscr{F}) = 2 - 2\rho(\mathcal{L}) > 4$$

thus \mathcal{E} has a nontrivial endomorphism $\varphi: \mathscr{F} \to \mathscr{F}$ meaning $\varphi \neq \lambda \mathrm{id}$. Choose a point $x \in X$ and let λ be an eigenvalue of $\varphi(x)$. Then $\psi = \varphi - \lambda \mathrm{id}$ is nonzero but is not of full rank at x. Thus $\det \psi \in \mathrm{Hom}_X (\det \mathcal{E}, \det \mathcal{E}) = H^0(X, \mathcal{O}_X)$ has a zero and hence is zero. Let $\mathcal{E}_1 = \mathrm{im} \, \psi$ and $\mathcal{E}_2 = \mathrm{coker} \, \psi$ so there is a sequence,

$$0 \longrightarrow \mathcal{E}_1 \longrightarrow \mathcal{E} \longrightarrow \mathcal{E}_2 \longrightarrow 0$$

so we have $c_1(\mathcal{E}) = c_1(\mathcal{E}_1) + c_1(\mathcal{E}_2)$ and $c_1(\mathcal{E}) = [C]$. Then if $c_1(\mathcal{E}_1)$ and $c_1(\mathcal{E}_2)$ are represented by nonzero effective divisors. We showed last time that \mathcal{E} is globally generated and $H^0(X, \mathcal{E}^{\vee}) = 0$. Thus since $\mathcal{E} \to \mathcal{E}_i$ we see that \mathcal{E}_i are globally generated so $c_1(\mathcal{E}_i) = [C_i]$ for some effective class C_i . (SHOW BOTH CLASSES ARE NONTRIVIAL). Hence $C \sim C_1 + C_2$ contradicting the assumption on the linear system.

6.2 Mukai's Theorem

Definition 6.2.1. Let X be a proper k-scheme. A vector bundle \mathcal{E} on X is simple if,

$$\operatorname{Hom}_X(\mathcal{E},\mathcal{E}) = k$$

Remark. Simple vector bundles are indecomposable. If X is geometrically irreducible then all line bundles are simple.

In this section, let X be a (smooth projective) K3 surface over \mathbb{C} . Therefore, all line bundles are simple.

Remark. If \mathcal{E} is simple, then by Serre duality using that $\omega_X \cong \mathcal{O}_X$,

$$\operatorname{Ext}_{X}^{2}\left(\mathcal{E},\mathcal{E}\right)\cong\operatorname{Ext}_{X}^{2}\left(\mathcal{E}\otimes\mathcal{E}^{\vee},\omega_{X}\right)=H^{0}(X,\mathcal{E}\otimes\mathcal{E}^{\vee})^{\vee}=\operatorname{Hom}_{X}\left(\mathcal{E},\mathcal{E}\right)^{\vee}=\mathbb{C}$$

Definition 6.2.2. Let $\mathcal{M}(X, r, c_1, c_2)$ be the moduli space of simple vector bundles on X of rank r and with Chern classes c_1 and c_2 .

Remark. Because the objects of \mathcal{M} are simple, the stabilizers groups are \mathbb{G}_m and hence $\mathcal{M} \to M$ is a \mathbb{G}_m -torsor over a coarse space M.

Remark. The moduli problem has tangent-obstruction theory at a point $\mathcal{E} \in \mathcal{M}$,

$$T^i = \operatorname{Ext}_X^i(\mathcal{E}, \mathcal{E})$$

Therefore, since the fiber direction $B\mathbb{G}_m$ have trivial tangent direction we see that,

$$T_{[\mathcal{E}]}M = \operatorname{Ext}_X^1(\mathcal{E}, \mathcal{E})$$

Remark. The cup product gives a nondegenerate holomorphic 2-form on M defined by,

$$\operatorname{Ext}_{X}^{1}\left(\mathcal{E},\mathcal{E}\right)\times\operatorname{Ext}_{X}^{1}\left(\mathcal{E},\mathcal{E}\right)\to\operatorname{Ext}_{X}^{2}\left(\mathcal{E},\mathcal{E}\right)=\mathbb{C}$$

Therefore, M gives an example of a holomorphic symplectic variety. When dim M=2 it turns out that M is also a K3 surface.

Theorem 6.2.3 (Mukai). The moduli space $M(X, r, c_1, c_2)$ is smooth.

Proof. By descent along the flat map $\mathcal{M} \to M$ it suffices to show that \mathcal{M} is smooth. Alternatively we can develop directly tangent-obstruction theory for M. Either way, it suffices to show that obstruction classes $ob(E) \in \operatorname{Ext}^2_X(\mathcal{E}, \mathcal{E})$ vanish. Let $\mathcal{E} \in \mathcal{M}$ be a closed point (corresponding to a simple vector bundle \mathcal{E} on X) and a small extension of Artin local k-algebras $A \subset B$,

$$\operatorname{Def}_{\mathcal{M}}(B) \longrightarrow \operatorname{Def}_{\mathcal{M}}(A) \xrightarrow{\operatorname{ob}} \operatorname{Ext}_{X}^{2}(\mathcal{E}, \mathcal{E}) \\
\downarrow^{\operatorname{det}} \qquad \qquad \downarrow^{\operatorname{tr}} \\
\operatorname{Def}_{\operatorname{Pic}}(B) \longrightarrow \operatorname{Def}_{\operatorname{Pic}}(A) \xrightarrow{\operatorname{ob}} \operatorname{Ext}_{X}^{2}(\mathcal{O}_{X}, \mathcal{O}_{X})$$

but Pic_X is smooth so we see that $tr \circ ob = 0$. However, using Serre duality,

$$\operatorname{Ext}_{X}^{2}\left(\mathcal{E},\mathcal{E}\right) \stackrel{\sim}{\longrightarrow} H^{0}(X,\mathcal{E}\otimes\mathcal{E}^{\vee}) \stackrel{\sim}{\longrightarrow} \operatorname{Hom}_{X}\left(\mathcal{E},\mathcal{E}\right)$$

$$\downarrow^{\operatorname{tr}} \qquad \qquad \downarrow^{\operatorname{tr}} \qquad \qquad \downarrow^{\operatorname{tr}}$$

$$\operatorname{Ext}_{X}^{2}\left(\mathcal{O}_{X},\mathcal{O}_{X}\right) \stackrel{\sim}{\longrightarrow} H^{0}(X,\mathcal{O}_{X}) = = = H^{0}(X,\mathcal{O}_{X})$$

but since \mathcal{E} is simple the map $\operatorname{tr}: \operatorname{Hom}_X(\mathcal{E}, \mathcal{E}) \to H^0(X, \mathcal{O}_X)$ is an isomorphism. Thus $\operatorname{tr} \circ \operatorname{ob} = 0$ implies that $\operatorname{ob} = 0$.

6.3 Proof of (b)

Sketch of Proof of (b). Recall that for $\mathcal{L} \in V_d^r(C')$ we know that the tangent space of $V_d^r(C')$ and $G_d^r(C')$ are isomorphic and hence injectivity of $\mu_{\mathcal{L}}$ is equivalent to $V_d^r(C')$ being smooth of the expected dimension. Consider the variety,

$$\mathcal{V}_d^r = \{(C', \mathcal{L}) \mid C' \in |C| \text{ smooth curve and } \mathcal{L} \in V_d^r(C')\}$$

and denote,

$$\pi_d^r: \mathcal{V}_d^r \to |C|$$

the natural map. By generic smoothness, to show that $V_d^r(C')$ is smooth (and hence $\mu_{\mathcal{L}}$ is injective) for a generic C' is suffices to show that \mathcal{V}_d^r is smooth.

Consider the fibration,

$$\pi: \mathcal{G} \to M = M(X, r+1, [C], d)$$

where \mathscr{G} is the space of pairs (\mathcal{E}, V) for a simple vector bundle \mathcal{E} of rank r+1 of X with $c_1(\mathcal{E}) = [C]$ and $c_2(\mathcal{E}) = d$ and $V \subset H^0(X, \mathcal{E})$ of dimension r+1. By Mukai's theorem M is smooth and hence \mathscr{G} is smooth since it is a Grassmannian bundle so we can compute the tangent space at the point $\mathcal{E} = \mathscr{F}_{C,\mathcal{E}}^{\vee}$ to get,

$$\dim \mathcal{G} = \dim M + (r+1)(\dim H^0(X,\mathcal{E}) - r - 1)$$

$$= \operatorname{Ext}_X^1(\mathcal{E},\mathcal{E}) + (r+1)(\dim H^0(X,\mathcal{E}) - r - 1)$$

$$= 2\rho(r,d,g) + (r+1)(g-d+r) = g + \rho(r,d,g)$$

using a lemma we proved last time. Thus it suffices to show that \mathcal{V}_d^r has an open embedding in \mathscr{G} .

Let $U \subset \mathcal{G}$ denote the open set consisting of pairs (E, V) such that,

- (a) E is globally generated and $H^1(X, E) = H^2(X, E) = 0$
- (b) the natural map ev : $V \otimes_{\mathbb{C}} \mathcal{O}_X \to \mathcal{E}$ drops rank on a smooth curve C_V and coker ev is a line bundle on C_V .

Then we have exact sequences,

$$0 \longrightarrow \mathcal{E}^{\vee} \longrightarrow V^{\vee} \otimes \mathcal{O}_X \longrightarrow \mathcal{L}_V \longrightarrow 0$$

$$0 \longrightarrow V \otimes \mathcal{O}_X \longrightarrow \mathcal{E} \longrightarrow \omega_C \otimes \mathcal{L}_V^{\vee} \longrightarrow 0$$

(WHY) SHOW THE EQUAIVALENCE

7 Oct 25

7.1 Setup

X is a smooth projective surface over \mathbb{C} and L a line bundle on X. Then we have the following two facts,

adjunction if $C \subset X$ is an effective curve then,

$$p_a(C) - 1 = \frac{1}{2}C \cdot (C + K_X)$$

Hodge index if D, H are divisors on X with $H^2 \ge 0$ and $D \cdot H = 0$ then $D^2 \le 0$ and $D^2 = 0$ iff $D \sim 0$.

Remark. If C is integral then $p_a(C) \geq 0$.

7.2 Linear Systems

Let $V \subset H^0(X, L)$ be a linear system. Then the base locus is,

$$Bs(V) = \{ p \in X \mid \forall s \in V : s(p) = 0 \in L(p) \}$$

Note we use the notation $L(p) = L_p/\mathfrak{m}_p L_p$. Consider the map,

$$\Phi_V: X \backslash \mathrm{Bs}(V) \to \mathbb{P}(V)$$

Note that $p \in Bs(V)$ iff $H^0(X, L) \to H^0(Z, \mathcal{L}|_Z)$ is zero.

Proposition 7.2.1. Bs(V) = \emptyset then $\Phi_V : X \to \mathbb{P}(V)$ is a closed embedding iff,

- (a) V separates points meaning $\forall p, q \in X$ with $p \neq q$ there is $s \in V$ with s(p) = 0 and $s(q) \neq 0$ or vice versa
- (b) V separates tangent directions,

$$\{s \in V \mid s_p \in \mathfrak{m}_p L_p\}$$

generates $\mathfrak{m}_p L_p/\mathfrak{m}_p^2 L_p$ as a vector space.

Remark. We can reformulate the conditions as follows,

(a) $p, q \in X$ with $p \neq q$ let $Z = \{p, q\}$ reduced thine,

$$H^0(X,L) \to H^0(Z,L|_Z)$$

is surjective

(b) $p \in X$ and $t \in \mathfrak{m}_p/\mathfrak{m}_p^2$ and Z is cut out by $\mathfrak{m}_p^2 + (t)$ locally then,

$$H^0(X,L) \to H^0(Z,L|_Z)$$

is surjective.

Theorem 7.2.2 (Reider). Let L be a nef line bundle,

- (a) let $(L \cdot L) \geq 5$. Let p be a base point of $|K_X + L|$. Then there is n effective divisor $D \subset X$ with $p \in D$ such that either,
 - (a) $(L \cdot D) = 0$ and $D^2 = -1$
 - (b) $(L \cdot D) = 1$ and $D^2 = 0$
- (b) $(L \cdot L) \geq 10$. Let $p \in X$ and $q \in X$ with $p \neq q$ which are not separated by $|K_X + L|$ or $q \in \mathfrak{m}_p/\mathfrak{m}_p^2$ and p, q not separated by $|K_X + L|$. Then there is an effective divisor $D \subset X$ with $Z_{p,q} \subset D$ such that one of the three conditions holds,
 - (a) $(L \cdot D) = 0$ and $(D \cdot D) \in \{-1, -2\}$
 - (b) $(L \cdot D) = 1$ and $(D \cdot D) \in \{0, -1\}$
 - (c) $(L \cdot D) = 2$ and $(D \cdot D) = 0$.

Example 7.2.3. Let $X = \mathbb{P}^2$ and $L = \mathcal{O}_X(2)$ then $(L \cdot L) = 4$ and $K_X = \mathcal{O}_X(-3)$ then $K_X + L = \mathcal{O}_X(-1)$ which has every point as a base point. Let $D \subset X$ and $D \in |kH|$ then $D^2 = k^2$ but $L \cdot D = 2k$ so these cannot satisfy the conclusion of the theorem. This shows that $(L \cdot L) \geq 5$ is strict in the theorem.

7.3 Fujita's Conjecture

Conjecture 7.3.1 (Fujita 1985). Let X be a compact complex manifold of dimension n and L an ample line bundle.

- (a) $m \ge n+1 \implies K_X \otimes L^{\otimes m}$ is base point free
- (b) $m \ge n + 2 \implies K_X \otimes L^{\otimes m}$ is very ample.

Proof in the n=2 case. (a) We know X is projective use Nkai-Moishecon. Let $(L \cdot L) \geq 1$ then mL is nef if $m \geq 3$ then $(mL \cdot mL) \geq 3^2 \geq 5$. Then is p is a base point of $|K_X + K|$ then there is an effective divisor $D \subset X$ with $p \in D$ such that $(mL \cdot D) = 0$ and $D^2 = 1$ or $(mL \cdot D) = 1$ which is not possible since m > 1 and hence we have $(L \cdot D) = 0$ and $D^2 = -1$. We write,

$$D = D_1 + \dots + D_r$$

But L is ample so $(D_i \cdot L) > 0$ and D must have some component since $p \in D$ and thus $(D \cdot L) > 0$ giving a contradiction.

(b) Use the same sort of argument with the second part of Reider's theorem.

7.4 Pluricanonical Mappings

Let X be a surface of general type. Consider the pluricanonical maps,

$$\Phi_m: X \dashrightarrow \mathbb{P}(H^0(mK_X))$$

defined by the complete linear system $|mK_X|$.

Proposition 7.4.1. If X is minimal then K_X is nef and $K_X^2 \ge 1$.

Definition 7.4.2. A (-2)-curve on X is a smooth rational curve $C \subset X$ with $C^2 = -2$.

Proposition 7.4.3. If X is minimal then X has finitely many -2-curves. In fact, it is at most $\rho(X) - 1$.

Theorem 7.4.4 (Bombieri). Let X be a minimal surface of general type. Let,

$$F = \bigcup C \subset X$$

be the union of the -2-curves.

- (a) if $m \ge 4$ or $m \ge 3$ and $K_X^2 \ge 2$ then Φ_m is a morphism
- (b) if $m \geq 5$ or $m \geq 4$ and $K_X^2 \geq 2$ or $m \geq 3$ and $K_X^2 \geq 3$ then Φ_m is an embedding on $X \setminus F$.

Proof. Let $L=(m-1)K_X$ is nef then $L \cdot L \geq 5$. Apply Reider's theorem. Let p be a base point of $|K_X + L| = |mK|$. Then there is an effective divisor $D \subset X$ with $p \in D$ such that $(L \cdot D) = 0$ and $D^2 = 1$ since $L \cdot D = 1$ is impossible. Then,

$$-1 = D^2 = D \cdot (D + K_X) = 2p_a(D) - 2$$

which is a contradiction.

7.5 Bogomolov's Theorem

Theorem 7.5.1 (Bogomolov). Let E be a vector bundle of rank e on a surface X. If $c_1(E)^2 > \frac{2e}{e-1}c_2(E)$ then E is H-unstable with respect to every ample class H.

Remark. $c_2(E) \in H^4(X,\mathbb{Z})$ so we view $c_2(E)$ as an integer under the canonical isomorphism $H^4(X,\mathbb{Z}) \xrightarrow{\sim} \mathbb{Z}$ using that X is oriented (as a complex manifold).

7.5.1 Stability for Curves

Let C be a smooth projective irreducible curve. Let E be a vector bundle on C.

Definition 7.5.2. The slope,

$$\mu(E) = \frac{\deg E}{\operatorname{rank} E}$$

where $\deg E = \deg \det E$.

Example 7.5.3. Let $C = \mathbb{P}^1$ then $\mu(\mathcal{O}_C) = 0$ and $\mu(\mathcal{O}_C(1)) = 1$ and,

$$\mu(\mathcal{O}_C(a) \oplus \mathcal{O}_C(b)) = \frac{a+b}{2}$$

Definition 7.5.4. Let $F \subset E$ be a coherent subsheaf. Then F is locally free of constant rank almost everywhere. Then $c_1(F) := \det F^{\vee\vee}$ is a line bundle

Definition 7.5.5. The slope of a torsion-free sheaf F is,

$$\mu(F) = \frac{\deg F}{\operatorname{rank} F}$$

Definition 7.5.6. *E* is *stable* if, for every $F \subset E$ with,

$$0 < \operatorname{rank} F < \operatorname{rank} E$$

we have $\mu(F) < F(E)$ and semistable if $\mu(F) < \mu(E)$.

Remark. It is trivial that line bundles are stable.

Example 7.5.7. Let $C = \mathbb{P}^1$ then $\mathcal{O} \oplus \mathcal{O}(1)$ is unstable because $\mathcal{O}(1) \subset \mathcal{O} \oplus \mathcal{O}(1)$,

$$\mu(\mathcal{O}(1)) > \mu(\mathcal{O} \oplus \mathcal{O}(1)) = \frac{1}{2}$$

Theorem 7.5.8. Let E be a vector bundle on C and L a line bundle on C,

- (a) E is (semi)-stable iff $E \otimes L$ is (semi)-stable
- (b) E is semistable, deg E < 0 implies $H^0(C, E) = 0$
- (c) if E is semi-stable then $\operatorname{Sym}_n(E)$ is semi-stable for $n \geq 1$.

Remark. The last statement is not true for stable instead of semi-stable or in positive characteristic.

7.5.2 Stability For Surfaces

Let H be an ample divisor on a surface X.

Definition 7.5.9. The H-slope is defined,

$$\mu_H(E) := \frac{c_1(E) \cdot H}{\operatorname{rank} E}$$

Definition 7.5.10. For $F \subset E$ we have $c_1(F) = \det F^{\vee\vee}$ is a reflexive sheaf of rank 1 and hence is a line bundle on a surface. Then we can set,

$$\mu_H(F) = \frac{c_1(F) \cdot H}{\operatorname{rank} F}$$

Definition 7.5.11. We say E is H-stable if for every $F \subset E$ with,

$$0 < \operatorname{rank} F < \operatorname{rank} E$$

if $\mu_H(F) < \mu_H(E)$ and semi-stable if $\mu_H(F) \leq \mu_H(E)$.

8 Nov. 1 Bogomolov's Theorem

Let (X, \mathcal{L}) be a polarized surface over \mathbb{C} .

Definition 8.0.1. A sheaf \mathscr{F} on X is called torsion-free if for all $U \subset X$ open, the group $\mathscr{F}(U)$ is torsion-free module over $\mathcal{O}_X(U)$.

Remark. Recall that $\mathscr{F}^{\vee} = \mathscr{H}om_{\mathcal{O}_X}(\mathscr{F}, \mathcal{O}_X)$. There is a natural morphism $\mathscr{F} \to \mathscr{F}^{\vee\vee}$.

Proposition 8.0.2. \mathscr{F} is torsion-free iff $\mathscr{F} \to \mathscr{F}^{\vee\vee}$ is injective.

Definition 8.0.3. We say that \mathscr{F} is reflexive if $\mathscr{F} \to \mathscr{F}^{\vee\vee}$ is an isomorpism.

Proposition 8.0.4. Any reflexive sheaf on a regular dim $X \leq 2$ scheme is locally free.

Example 8.0.5. Let $p \in |X|$ be a closed point and $\mathscr{I}_p \hookrightarrow \mathcal{O}_X$ the sheaf of ideals. Then \mathscr{I}_p is torsion-free but not locally-free.

Definition 8.0.6. The rank of a torsion-free sheaf \mathscr{F} is defined to be,

$$\operatorname{rank} \mathscr{F} = \ell(\mathscr{F}_{\operatorname{\acute{e}t}})$$

where $\eta \in X$ is the generic point.

Definition 8.0.7. A sheaf \mathscr{F} is called μ -semistable (with respect to \mathscr{L}) if \mathscr{F} is torsion-free for all nontrivial proper subsheaves $\mathscr{E} \subset \mathscr{F}$ we have,

$$\frac{c_1(\mathcal{E}) \cdot c_1(\mathcal{L})}{\operatorname{rank} \mathcal{E}} \le \frac{c_1(\mathcal{L}) \cdot c_1(\mathscr{F})}{\operatorname{rank} \mathscr{F}}$$

Remark. For the definition of μ -stable you need nontrivial proper subsheaves with strictly smaller rank. To see why this is necessary, consider,

$$0 \longrightarrow \mathscr{I}_p \longrightarrow \mathscr{O}_X \longrightarrow k_p \longrightarrow 0$$

Then we get $c_1(\mathscr{I}_p) = 0$ and hence we don't get a strict inequality,

$$\frac{c_1(\mathscr{I}_p) \cdot c_1(\mathcal{L})}{\operatorname{rank} \mathscr{I}_p} \le \frac{c_1(\mathcal{O}_X) \cdot c_1(\mathcal{L})}{\operatorname{rank} \mathcal{O}_X}$$

Example 8.0.8. (a) if \mathscr{F} has rank 1 then \mathscr{F} is μ -semistable for all polarizatios

- (b) if \mathscr{F} is μ -semistable and $\mathscr{H} \in \operatorname{Pic} X$ then $F \otimes \mathscr{H}$ is μ -semistable
- (c) if \mathscr{F} is μ -semistable then $\mathscr{F}^{\vee\vee}$ is μ -semistable.

Definition 8.0.9. Let \mathscr{F} be torsion-free of rank r, then $\Delta(\mathscr{F}) = 2rc_2 - (r-1)c_1^2$.

Theorem 8.0.10 (Bogomolov). If \mathscr{F} is μ -semistable on (X, \mathcal{L}) then $\Delta(\mathscr{F}) \geq 0$.

Remark. Since $\Delta(\mathcal{F})$ is independent of the polarization, Bogomolov's theorem gives an obstruction to be μ -semistable with respect to any polarization.

Proposition 8.0.11. Recall,

$$\operatorname{char} \mathscr{F} = \operatorname{rank} \mathscr{F} + c_1(\mathscr{F}) + \frac{1}{2}(c_1^2 - 2c_2)$$

Then we can compute with $r = \operatorname{rank} \mathscr{F}$,

$$\log\left(\frac{\operatorname{char}\mathscr{F}}{r}\right) = \log\left(1 + \Box\right) = \left[\frac{c_1}{r} + \frac{c_1^2 - 2c_2}{2r}\right] - \frac{c_1^2}{2r} = \frac{c_1}{r} + \frac{1}{2r^2}\left((r-1)c_1^2 - 2rc_2\right)$$

Therefore,

$$\log\left(\frac{\operatorname{char}\mathscr{F}}{r}\right) = \frac{c_1}{r} + \frac{1}{2r^2}\Delta(\mathscr{F})$$

Because log sends multiplication to addition, we have,

$$\frac{\Delta(\mathscr{F}\otimes\mathscr{G})}{(\operatorname{rank}\mathscr{F})^2(\operatorname{rank}\mathscr{G})^2} = \frac{\Delta(\mathscr{F})}{(\operatorname{rank}\mathscr{F})^2} + \frac{\Delta(\mathscr{G})}{(\operatorname{rank}\mathscr{G})^2}$$

Proposition 8.0.12. (a) if \mathscr{F} is a line bundle then $\Delta(\mathscr{F}) = 0$

- (b) if \mathscr{F} is locally free then $\Delta(\mathscr{F}) = \Delta(\mathscr{F}^{\vee})$
- (c) for $\mathcal{H} \in \text{Pic}X$ we have,

$$\frac{\Delta(\mathscr{F}\otimes\mathscr{H})}{(\operatorname{rank}\mathscr{F})^2 1^2} = \frac{\Delta(\mathscr{F})}{(\operatorname{rank}\mathscr{F})^2} + 0 \implies \Delta(\mathscr{F}\otimes\mathscr{H}) = \Delta(\mathscr{F})$$

- (d) if \mathscr{F} is locally free, then $\Delta(\operatorname{End}(\mathscr{F})) = 2(\operatorname{rank}\mathscr{F})^2\Delta(\mathscr{F})$
- (e) if \mathscr{F} is torsion free, then,

$$0 \longrightarrow \mathscr{F} \longrightarrow \mathscr{F}^{\vee\vee} \longrightarrow \mathscr{Q} \longrightarrow 0$$

and then,

$$\Delta(\mathscr{F}^{\vee\vee}) = 2rc_2(\mathscr{F}^{\vee\vee}) - (c-1)c_1(\mathscr{F}^{\vee\vee}) = 2r(c_2(\mathscr{F}) + \ell(\mathcal{Q})) - (r-1)c_1(\mathscr{F})^2 = \Delta(\mathscr{F}) + 2r\ell(\mathcal{Q})$$

Remark. By the last property, since $\ell(\mathcal{Q}) \geq 0$ we see that if $\Delta(\mathscr{F}^{\vee\vee}) \leq 0$ then $\Delta(\mathscr{F}) \leq 0$. Therefore, it suffices to prove the theorem for reflexive and hence locally free \mathscr{F} ,

Proof. Proof reductions,

- (a) can assume $\mathscr{F} \cong \mathscr{F}^{\vee\vee}$ by above remark
- (b) $\Delta(\text{End}(\mathscr{F})) = 2r^2\Delta(\mathscr{F})$ so can assume that $\det \mathscr{F} = \mathcal{O}_X$.

We need to show that $c_2(\mathscr{F}) \leq 0$ for \mathscr{F} such that,

- (a) \mathcal{F} is a vector bundle
- (b) $\det \mathscr{F} \cong \mathcal{O}_X$
- (c) \mathscr{F} is μ -semistable for some \mathscr{L} .

Consider,

$$\mathscr{F}_n = \operatorname{Sym}_{nr}(\mathscr{F})$$

We use the following lemmas.

Lemma 8.0.13. (a) det $\mathscr{F}_n \cong \mathcal{O}_X$

(b) there is a formula,

$$\chi(X, \mathscr{F}_n) = -\frac{\Delta(\mathscr{F})n^{r+1}r^r}{2(r+1)!} + O(n^r)$$

Proof. Represent \mathscr{F} as $[\xi] \in H^1(X, \operatorname{SL}_n)$ because $\det \mathscr{F} \cong \mathcal{O}_X$. Then $\operatorname{SL}_r \subset \operatorname{Sym}_{nr}(\mathbb{C}^r)$ gives an action $\operatorname{SL}_r \subset \det \operatorname{Sym}_{nr}(\mathbb{C}^r)$ which is a character of SL_r and hence is trival. Therefore, the map $H^1(X, \operatorname{SL}_r) \to H^1(X, \mathbb{G}_m)$ given by taking determinants is trivial.

Consider, $\pi : \mathbb{P}_X(\mathscr{F}) \to X$. Look at $\mathcal{O}_{\mathbb{P}(\mathscr{F})}(1)$. Then,

$$\chi(\mathbb{P}(\mathscr{F}),\mathcal{O}_{\mathbb{P}(\mathscr{F})}(nr)) = \chi(X,R\pi_*\mathcal{O}_{\mathbb{P}(\mathscr{F})}(nr)) = \chi(X,\mathrm{Sym}_{nr}(\mathscr{F})) = \chi(X,\mathscr{F}_n)$$

Now, by Riemann-Roch we have,

$$\chi(\mathbb{P}(\mathscr{F}), \mathcal{O}_{\mathbb{P}(\mathscr{F})}(nr)) = \frac{(nr)^{r+1}c_1(\mathcal{O}_{\mathbb{P}(\mathscr{F})}(1))^{r+1}}{(r+1)!} + O(n^r)$$

But by the projective bundle formula (or the Grothendieck definition of Chern classes),

$$c_1(\mathcal{O}_{\mathbb{P}(\mathscr{F})}(1))^r - \pi^*c_1(\mathscr{F})c_1(\mathcal{O}_{\mathbb{P}(\mathscr{F})}(1))^{r-1} + \pi^*c_2(\mathscr{F})c_1(\mathcal{O}_{\mathbb{P}(\mathscr{F})}(1))^{r-2} = 0$$

We assumed that $c_1(\mathscr{F}) = 0$. Therefore,

$$c_1(\mathcal{O}_{\mathbb{P}(\mathscr{F})}(1))^{r+1} = -\pi^* c_2(\mathscr{F}) c_1(\mathcal{O}_{\mathbb{P}(\mathscr{F})}(1))^{r-1}$$

Now we have,

$$\deg (c_1(\mathcal{O}_{\mathbb{P}(\mathscr{F})}(1))^{r+1}) = -\deg \pi_*(\pi^*c_2(\mathscr{F})c_1(\mathcal{O}_{\mathbb{P}(\mathscr{F})}(1))^{r-1}) = -\deg (c_2(\mathscr{F}) \cdot \pi_*[c_1(\mathcal{O}_{\mathbb{P}(\mathscr{F})}(1)^{r-1})])$$

Now $\pi_*[c_1(\mathcal{O}_{\mathbb{P}(\mathscr{F})}(1))^{r-1}] = [X]$ since on each fiber since this is H^{r-1} on \mathbb{P}^{r-1} where H is the hyperplane class. Since $c_1(\mathscr{F}) = 0$ we have $\Delta(\mathscr{F}) = 2rc_2(\mathscr{F})$ and thus,

$$\chi(X, \mathscr{F}_n) = -\frac{\Delta(\mathscr{F})n^{r+1}r^r}{2(r+1)!} + O(n^r)$$

Remark. We explicitly complete the GRR calculation. Let $\widetilde{X} = \mathbb{P}_X(\mathscr{F})$. By GRR,

$$\chi(\widetilde{X}, \mathscr{G}) = \deg\left(\operatorname{char}(\mathscr{G}) \cdot \operatorname{td}_{\widetilde{X}}\right)$$

and because $R\pi_*\mathcal{O}_{\widetilde{X}}(nr) = \operatorname{Sym}_{nr}(\mathscr{F})[0]$ we have that,

$$\chi(X, \operatorname{Sym}_{nr}(\mathscr{F})) = \chi(X, R\pi_*\mathcal{O}_{\widetilde{X}}(nr)) = \chi(\widetilde{X}, \mathcal{O}_{\widetilde{X}}(nr)) = \operatorname{deg}\left(\operatorname{char}(\mathcal{O}_{\widetilde{X}}(nr)) \cdot \operatorname{td}_{\widetilde{X}}\right)$$

Now let $\xi = c_1(\mathcal{O}_{\widetilde{X}}(1))$ then we see,

$$\chi(X, \operatorname{Sym}_{nr}(\mathscr{F})) = \operatorname{deg}\left(e^{nr\xi} \cdot \operatorname{td}_{\widetilde{X}}\right)$$

Let $d = \dim \widetilde{X} = r - 1 + \dim X = r + 1$. Then the leading term as a polynomial in n gives,

$$\chi(X, \operatorname{Sym}_{nr}(\mathscr{F})) = \frac{(nr)^d \xi^d}{d!} \cdot 1 + O(n^{d-1})$$

because the first term of $\mathrm{td}_{\widetilde{X}}$ is 1. This gives,

Proof. Now we complete the proof. From the lemma, to show that $\Delta(\mathscr{F}) \leq 0$ it suffices to show that $\chi(X, \mathscr{F}_n) \leq Cn^r$ as $n \to \infty$. This will follow if we show that $H^0(X, \mathscr{F}_n) \leq C_1 n^r$ as $n \to \infty$ and $H^2(X, \mathscr{F}_n) \leq C_2 n^r$ as $n \to \infty$.

9 Nov 15

From $\varphi: C \to \mathbb{P}^{g-1}$ the canonical morphism we get,

$$0 \longrightarrow T_C \longrightarrow \varphi^* T_{\mathbb{P}^{g-1}} \longrightarrow \mathcal{N}_C \longrightarrow 0$$

Theorem 9.0.1. Let $k = \bar{k}$ and $g \neq 2, 4, 6$ and C general canonical curve of genus g then \mathcal{N}_C is semi-stable.

Remark. rank $\mathcal{N}_C = g - 2$ then $\deg \varphi^* T_{\mathbb{P}^{g-1}} = 2g(g-1)$ and thus $\deg \mathcal{N}_C = (g+1)2(g-1) - 2(g^1-1)$. Therefore,

$$\mu(\mathcal{N}_C) = \frac{2(g^2 - 4 + 3)}{g - 2} = 2(g + 2) + \frac{6}{g - 2}$$

Example 9.0.2. g = 3 then $C \subset \mathbb{P}^2$ is a plane quartic and $\mathcal{N}_C \cong \mathcal{O}_C(4)$ is semistable.

Example 9.0.3. g = 5 then $C \subset \mathbb{P}^4$ is $C = Q_1 \cap Q_2 \cap Q_3$ is a complete intersection of three quadrics. Then $\mathcal{N}_C = \mathcal{O}_C(2)^{\oplus 3}$ is semi-stable.

Example 9.0.4. Let g=4 then $C=Q\cap X_3\subset \mathbb{P}^3$ so $\mathcal{N}_C\cong \mathcal{O}_C(2)\oplus \mathcal{O}_C(3)$ is destabilized.

Example 9.0.5. Let g=6 then $C \subset X \subset \mathbb{P}^5$ where X is a del-Pezzo surface, the blowup of \mathbb{P}^2 at three points anticanonically embedded in \mathbb{P}^5 and C is a quartic section. Then $\mathcal{N}_{C/X} \subset \mathcal{N}_C$ will destabilize it.

Remark. The g = 7 case is Aprodu-Farkas-Ortega. The g = 8 case by Bruns.

If (6, g - 2) = 1 then any sub $\mathscr{F} \subset \mathcal{N}_C$ has rank $\mathscr{F} \leq g - 3$ and hence \mathcal{N}_C is stable because equality is impossible since the fraction $\mu(\mathcal{N}_C)$ is irreducible.

Corollary 9.0.6. $g \equiv 1, 3 \mod 6$ then \mathcal{N}_C is stable.

Let C be a connected nodal curve. Let V be a vector bundle on C. Then consider the normalization $\nu: \widetilde{C} \to C$. Let \widetilde{p}_1 and \widetilde{p}_2 be the two preimages of the node. There is a canonical isomorphism,

$$\nu^*V|_{\widetilde{p}_1} \xrightarrow{\sim} \nu^*V|_{\widetilde{p}_2}$$

and $\mathscr{F} \subset \nu^*V$ a subbundle then it makes sense to compare $\mathscr{F}|_{\widetilde{p}_1}$ and $\mathscr{F}|_{\widetilde{p}_2}$.

Definition 9.0.7. The adjusted slope of $\mathscr{F} \subset \nu^*V$ is,

$$\mu_C^{\mathrm{adj}}(\mathscr{F}) = \mu(\mathscr{F}) - \frac{1}{\mathrm{rank}\,\mathscr{F}} \sum_{p \in C^{\mathrm{sing}}} \mathrm{codim}\,(\mathscr{F}|_{\widetilde{p}_1} \cap \mathscr{F}_{\widetilde{p}_2})\,\mathscr{F}|_{\widetilde{p}_1}$$

Say V is semi-stable on C if,

$$\mu_C^{\mathrm{adj}}(\mathscr{F}) \le \mu^{\mathrm{adj}}(nu^*V) = \mu(V)$$

for any subbunle (of constant rank) $\mathscr{F} \subset \nu^*V$ and stable if there is a strict inequality for nontrivial subbundles.

Proposition 9.0.8 (CIV, 2022). Let $\mathcal{C} \to \Delta = \operatorname{Spec}(R)$ be a family of connected nodal curves over a DVR. Let V be a vector bundle on \mathcal{C} and V_0 is semistable on \mathcal{C}_0 then V_{η} is semistable on \mathcal{C}_{η} .

Lemma 9.0.9. Let $C = X \cup Y$ be nodal. Let V be a vector bundle with $V|_X$ and $V|_Y$ semistable. Then V is semistable. Furthermore, if one of $V|_X$ and $V|_Y$ is stable, then V is stable.

10 Nov 29 Reider's Theorem

Theorem 10.0.1. Let X be a surface and L a nef line bundle.

- (a) if $L^2 > 4$ and p is a base point of $K_X \otimes L$ then there is some $p \in D \subset X$ effective such that one of
 - (a) $L \cdot D = 0$ and $D^2 = -1$
 - (b) $L \cdot D = 1 \text{ and } D^2 = 0$

is true

(b) if $L^2 > 9$ and p, q are not separated by $K_X \otimes L$ then there is $p, q \in D \subset X$ such that one of,

- (a) $L \cdot D = 0$ and $D^2 = -1, -2$
- (b) $L \cdot D = 1$ and $D^2 = 0, -1$
- (c) $L \cdot D = 2$ and $D^2 = 0$

is true.

Proof. Step 1: build an extension,

$$0 \longrightarrow \mathcal{O}_X \longrightarrow E \longrightarrow I_Z \otimes L \longrightarrow 0$$

with $Z = \{p\}$ or $\{p, q\}$ and E locally free.

Step 2: use Bogomolov inequality, to show that E is unstable and we can find a sequence that destabilizes E,

$$0 \longrightarrow A \longrightarrow E \longrightarrow I_W \otimes V \longrightarrow 0$$

for every ample class. The fact that it destabilizes for every ample is important because then we can derive results for nef classes by taking limits.

10.1 Special Cycles

Definition 10.1.1. Let X be a variety and $\mathcal{O}_X(D)$ a line bundle on X. An zero-dimesional subscheme $Z \subset X$ is said to be in special position with respect to $\mathcal{O}_X(D)$ if

- (a) $H^0(X, \mathcal{O}_X(D)) \to H^0(Z, \mathcal{O}_X(D)|_Z)$ is not surjective
- (b) for all $Z' \subset Z$ with $\operatorname{length}_{\mathcal{O}_Z/\mathcal{O}_{Z'}} (=) 1$ the map

$$H^0(X, \mathscr{I}_Z(D)) \to H^0(X, \mathscr{I}_{Z'}(D))$$

is an isomorphism

Lemma 10.1.2. Suppose that $\mathcal{O}_X(D)$ does not separate some collection of m distinct points on U. Then there exists a reduced zero-dimensional subscheme $Z \subset U$ with length_Z (\leq) m in special position with respect to $\mathcal{O}_X(D)$.

Proof. Let $Z_0 = \{p_1, \ldots, p_m\}$ be some collection of m distinct points in U such that

$$H^0(X, \mathcal{O}_X(D)) \to H^0(Z_0, \mathcal{O}_X(D)|_{Z_0})$$

is not surjective. For each $p_i \in Z_0$ let $Z_0' = Z_0 \setminus \{p_i\}$ and consider the map

$$H^0(X,\mathscr{I}_{Z_0'}(D))\to H^0(X,\mathscr{I}_{Z_0}(D))$$

if this is an isomorphism for all i then Z_0 is in special position. Otherwise, there is i for which it is not an isomorphims. This means there is a section s vanishing on Z'_0 nonvanishing at p_i . If $\mathcal{O}_X(D)$ separates Z'_0 then it also separates Z_0 because we can use s to make the value at p_i anything without changing the values on Z'_0 . Thus $Z_1 := Z'_0$ is a collection of points not separated by $\mathcal{O}_X(D)$. Repeating, we get Z_k with length m-k in special position. The only case where this might fail is if we get down to k=m-1. Then $\mathcal{O}_X(D)$ is not globally generated on U. Since every section vanishing at some p then $Z = \{p\}$ is in special position so we automatically win.

IS THIS THE SAME AS Z SCHEME?

Theorem 10.1.3. Let S be a smooth surface, L a line bundle and Z an effective zero-cycle on S. The following are equivalent:

- (a) Z is in special position with respect to $|K_S + L|$, where K_S is the canonical divisor of S,
- (b) there exist a pair (\mathcal{E}, e) where \mathcal{E} is a rank 2 bundle on S and e a section such that $\mathcal{E} = \wedge^2 \mathcal{E} = L$ and V(e) = Z.

Proof. Let Z be in special position. Then consider the extension

$$0 \to \mathcal{O}_S \to \mathcal{E} \to \mathscr{I}_Z \otimes L \to 0$$

whose extension class in

$$\operatorname{Ext}_S^1(\mathscr{I}_Z \otimes L, \mathscr{O}_S) = H^1(X, \mathscr{I}_Z \otimes L \otimes \omega_S)^{\vee}$$

is the element defined by

$$H^0(Z, L \otimes \omega_S|_Z) \to H^1(X, \mathscr{I}_Z \otimes L \otimes \omega_S)$$

DO THIS

For step 2 we have,

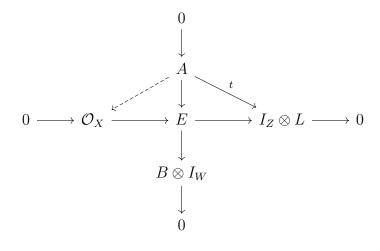

$$0 \longrightarrow \mathcal{O}_X \longrightarrow E \longrightarrow I_Z \otimes L \longrightarrow 0$$

and rank E = 2 and $\det E = L$ and $c_1(E) = c_1(L)$ and $c_2(E) = \deg Z = 1$ (doing part 1). Notice that $c_1(E)^2 > 4c_2(E)$. Then by Bogomolov, there is a sequence

$$0 \longrightarrow A \longrightarrow E \longrightarrow I_W \otimes B \longrightarrow 0$$

W is a 0-dimensional subscheme such that

- (a) $A \otimes B = L$
- (b) $(c_1(A) c_1(B))^2 > 0$
- (c) for any ample H we have $c_1(A) \cdot H > c_1(B) \cdot H$
- (d) $c_2(\mathcal{E}) = \operatorname{length}_Z(=) A \cdot B + \operatorname{length}_W($. Then consider the diagram,

Claim $t \neq 0$ otherwise, there a nonzero map $A \to \mathcal{O}_X$ and thus $H^0(X, A^{\vee}) \neq 0$ but $0 < (A - B) \cdot H = (2A - L) \cdot H$ and hence $(-A) \cdot H < -\frac{1}{2}L \cdot H \leq 0$ is a contradiction. Therefore $t \neq 0$.

Let D be the effective divisor defined by t. Since $Z \subset D$ and $L = A \otimes \mathcal{O}_X(D)$ so consider the sequence,

$$0 \longrightarrow I_Z \otimes L \otimes A^{\vee} \longrightarrow L \otimes A^{\vee} \longrightarrow (L \otimes A^{\vee})|_Z \longrightarrow 0$$

Now we enter step 3. Since A + B = L we can replace B by D i.e. ensure that B is effective. We have constructed divisors L, A, D with L - A = D thus A - D = L - 2D

Lemma 10.1.4. We have $L \cdot D \geq 0$ and $L \cdot D - 1 \leq D^2 \leq \frac{1}{2}L \cdot D$

Proof. Since D is effective and L is nef $L \cdot D \ge 0$. Since L is a limit of ample divisors we see that $L \cdot (A - D) \ge 0$ but L = A + D so $A^2 \ge D^2$ WHY DO THEY SAY NOT EQUALITY ALLOWED. Also

$$(A-D)^2 > 0 \implies A^2 - 2A \cdot D + D^2 \ge$$

Then $A \cdot D + \operatorname{length}_{W}(=) \operatorname{length}_{Z}(=) 1$ implies $A \cdot D \leq 1$. Hodge index theorem gives

$$A^2D^2 \le (A \cdot D)^2 \le 1$$

and thus $D^2 \leq 0$ since $A^2 \geq D^2$ WHY?

Now
$$0 \le L \cdot D = A \cdot D + D^2$$

11 A Langer: On boundedness of semistable sheaves

Let X be a projective varierty over $k = \bar{k}$. Fix some ample class H on X then we get slop semistability for torsion-free sheaves H-semistability.

Theorem 11.0.1 (Boundedness). Let $P \subset \mathbb{Q}[n]$ be an integer valued polynomial. Then the set,

$$S = \{H\text{-semistable torsor-free sheaves with Hilbert polynomial } P\}$$

is bounded i.e. there is a scheme Y of finite type over k and a sheaf \mathscr{F} on $X \times_k Y$ such that for all $\mathscr{G} \in S$ there is a k-point $y \in Y(k)$ such that $\mathscr{F}_y \cong \mathscr{G}$.

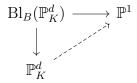

Bogomolov's inequality for $\mathbb{P}^d_K \Longrightarrow$ some restriction theorem for sheaves on $\mathbb{P}^d_k \Longrightarrow$ boundedness of H-semistable sheaves.

The main result of Langer is to prove Bogomolov's inequality for \mathbb{P}^d_K . Strategy: induction of the dimension d by using pencils.

Theorem 11.0.2 (Bogomolov Inequality). If \mathscr{F} is H-semistable, then,

$$\Delta(\mathscr{F})\cdot H^{d-2} = \left(2\operatorname{rank}\left(\mathscr{F}\right)\cdot c_2(\mathscr{F}) - (\operatorname{rank}\mathscr{F}-1)c_1(\mathscr{F})^2\right)\cdot H^{n-2} \geq 0$$

Proof. Start with \mathscr{F} on \mathbb{P}^d_K . Choose a general pencil $\mathbb{P}^1 \cong \Lambda \subset |\mathcal{O}_{\mathbb{P}^d_K}(1)|$ which has base locus $B \subset \mathbb{P}^d_K$. Blow it up,

Now you show that Bogomolov for the blowup with respt to the (now not ample) pullback of H. The fibers are projective spaces so we can reduce to smaller dimension.
